

Freezing of infested pork muscle kills cysticerci.

.

A method for culturing cysticerci that allows successful evagination and growth of scolexes from metacestodes of *Taenia solium* was used to study the survival of cysticerci subjected to low temperatures. Refrigeration of pork muscle infested with cysticerci at temperatures above 0 degrees C did not affect the parasites' survival in culture. Conversely, freezing of meat prevented survival of cysts. A practical procedure to kill cysticerci is the storage of pork muscle for four days at -5 degrees C, three days at -15 degrees C, or one day at -24 degrees C. These simple measures would help prevent the most frequent parasitosis of man's central nervous system.
